

Galvanically isolated 4 A single gate driver for SiC MOSFETs

SO-8W

Product status link

[STGAP2SICS](#)

Product label

Features

- High voltage rail up to 1200 V
- Driver current capability: 4 A sink/source @25°C
- dV/dt transient immunity ± 100 V/ns in full temperature range
- Overall input-output propagation delay: 75 ns
- Separate sink and source option for easy gate driving configuration
- 4 A Miller CLAMP dedicated pin option
- UVLO function
- Gate driving voltage up to 26 V
- 3.3 V, 5 V TTL/CMOS inputs with hysteresis
- Temperature shut-down protection
- Standby function
- 6 kV galvanic isolation
- Wide body SO-8W package
- UL 1577 recognized

Description

The **STGAP2SICS** is a single gate driver which provides galvanic isolation between the gate driving channel and the low voltage control and interface circuitry.

The gate driver is characterized by 4 A capability and rail-to-rail outputs, making the device also suitable for mid and high power applications such as power conversion and motor driver inverters in industrial applications. The device is available in two different configurations. The configuration with separated output pins allows to independently optimize turn-on and turn-off by using dedicated gate resistors. The configuration featuring single output pin and Miller CLAMP function prevents gate spikes during fast commutations in half-bridge topologies. Both configurations provide high flexibility and bill of material reduction for external components.

The device integrates protection functions: UVLO with optimized value for SiC MOSFETs and thermal shut down are included to facilitate the design of highly reliable systems. Dual input pins allow the selection of signal polarity control and implementation of HW interlocking protection to avoid cross-conduction in case of controller malfunction. The input to output propagation delay is less than 75 ns, which delivers high PWM control accuracy. A standby mode is available to reduce idle power consumption.

6 Functional description

6.1 Gate driving power supply and UVLO

The STGAP2SiCS is a flexible and compact gate driver with 4 A output current and rail-to-rail outputs. The device allows implementation of either unipolar or bipolar gate driving.

Figure 5. Power supply configuration for unipolar and bipolar gate driving

Undervoltage protection is available on VH supply pin. A fixed hysteresis sets the turn-off threshold, thus avoiding intermittent operation.

When VH voltage falls below the VHoff threshold, the output buffer enters a “safe state”. When VH voltage reaches the VHon threshold, the device returns to normal operation and sets the output according to actual input pins status.

The VDD and VH supply pins must be properly filtered with local bypass capacitors. The use of capacitors with different values in parallel provides both local storage for impulsive current supply and high-frequency filtering. The best filtering is obtained by using low-ESR SMT ceramic capacitors and are therefore recommended. A 100 nF ceramic capacitor must be placed as close as possible to each supply pin, and a second bypass capacitor with value in the range between 1 μ F and 10 μ F should be placed close to it.

6.2 Power-up, power-down and “safe state”

The following conditions define the “safe state”:

- GOFF = ON state;
- GON = High Impedance;
- CLAMP = ON state (for STGAP2SiCSC);

Such conditions are maintained at power-up of the isolated side ($VH < VH_{on}$) and during whole device power down phase ($VH < VH_{off}$), regardless of the value of the input pins.

The device integrates a structure which clamps the driver output to a voltage not higher than SafeClp when VH voltage is not high enough to actively turn the internal GOFF MOSFET on. If VH positive supply pin is floating or not supplied the GOFF pin is therefore clamped to a voltage smaller than SafeClp.

If the supply voltage VDD of the control section of the device is not supplied, the output is put in safe state, and remains in such condition until the VDD voltage returns within operative conditions.

After power-up of both isolated and low voltage sides, the device output state depends on the status of the input pins.

6.3 Control inputs

The device is controlled through the IN+ and IN- logic inputs, in accordance with the truth table below.

Table 9. Inputs truth table (applicable when device is not in UVLO or "safe state")

Input pins		Output pins	
IN+	IN-	GON	GOFF
L	L	OFF	ON
H	L	ON	OFF
L	H	OFF	ON
H	H	OFF	ON

A deglitch filter allows input signals with duration shorter than t_{deglitch} to be ignored, thereby preventing noise spikes potentially present in the application from generating unwanted commutations.

6.4 Miller Clamp function

The Miller clamp function allows the control of the Miller current during the power stage switching in half-bridge configurations. When the external power transistor is in the OFF state, the driver operates to avoid the induced turn-on phenomenon that may occur when the other switch in the same leg is being turned on, due to the C_{GD} capacitance.

During the turn-off period the gate of the external switch is monitored through the CLAMP pin. The CLAMP switch is activated when gate voltage goes below the voltage threshold, V_{CLAMPth} , thus creating a low impedance path between the switch gate and the GNDISO pin.

6.5 Watchdog

The isolated HV side has a watchdog function in order to identify when it is not able to communicate with LV side, for example because the VDD of the LV side is not supplied. In this case the output of the driver is forced in "safe state" until communication link is properly established again.

6.6 Thermal shutdown protection

The device provides a thermal shutdown protection. When junction temperature reaches the T_{SD} temperature threshold, the device is forced in "safe state". The device operation is restored as soon as the junction temperature is lower than $T_{SD}-T_{\text{hys}}$.

6.7 Standby function

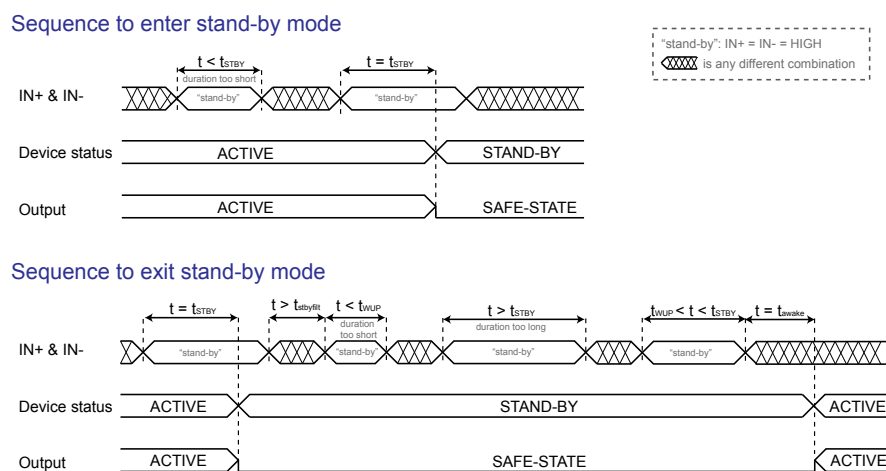

In order to reduce the power consumption of both control interface and gate driving sides the device can be put in standby mode. In standby mode the quiescent current from VDD and VH supply pins is reduced to I_{QDDSBY} and I_{QHSHBY} respectively, and the output remains in “safe state” (the output is actively forced low).

The way to enter standby is to keep both IN+ and IN- high (“standby” value) for a time longer than t_{STBY} . During stand-by the inputs can change from the “standby” value.

To exit stand-by, IN+ and IN- must be put in any combination different from the “standby” value for a time longer than $t_{stbyfilt}$, and then in the “standby” value for a time t such that $t_{WUP} < t < t_{STBY}$.

When the input configuration is changed from the “standby” value the output is enabled and set according to input state after a time t_{awake} .

8 Layout

8.1 Layout guidelines and considerations

In order to optimize the PCB layout, the following considerations should be taken into account:

- SMT ceramic capacitors (or different types of low-ESR and low-ESL capacitors) must be placed close to each supply rail pins. A 100 nF capacitor must be placed between VDD and GND and between VH and GNDISO, as close as possible to device pins, in order to filter high-frequency noise and spikes. In order to provide local storage for pulsed current, a second capacitor with a value between 1 μ F and 10 μ F should also be placed close to the supply pins.
- It is good practice to add filtering capacitors close to logic inputs of the device (IN+, IN-), particularly for fast switching or noisy applications.
- The power transistors must be placed as close as possible to the gate driver to minimize the gate loop area and inductance that might carry noise or cause ringing.
- To avoid degradation of the isolation between the primary and secondary side of the driver, there should not be any trace or conductive area below the driver.
- If the system has multiple layers, it is recommended to connect the VH and GNDISO pins to internal ground or power planes through multiple vias of adequate size. These vias should be located close to the IC pins to maximize thermal conductivity.

8.2 Layout example

An example of STGAP2SiCSC half-bridge suggested PCB layout with main signals highlighted by different colors is shown in Figure 11. It is recommended to follow this example for correct positioning and connection of filtering capacitors.
